

Denoising and Covariance Estimation of Cryo-EM Images

Tejal Bhamre

Princeton University

Joint work with Teng Zhang (UCF) and Amit Singer (Princeton)

June 10, 2016

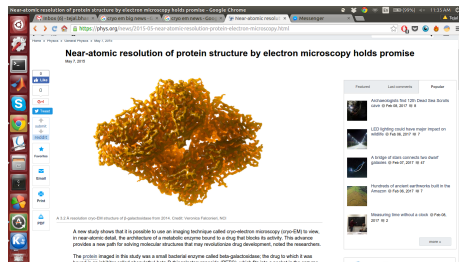

Why cryo-EM?

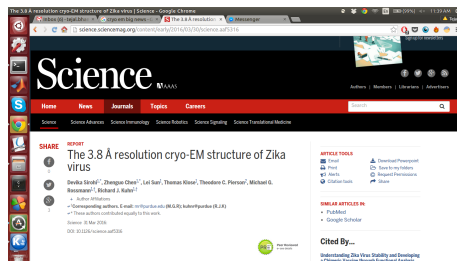

- 3D structure of macromolecules - understand function - drug discovery for cancer, AIDS, HIV, etc.
- X ray crystallography: many proteins, viruses resistant to crystallization (HIV virus)
- Cryo-EM: native state
- Can study structures impossible before!

Nature Method of the Year 2015

Cancer

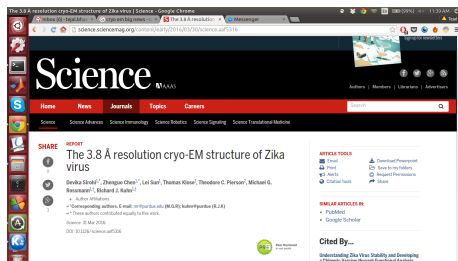

3D from 2D

- Flash freeze sample in an ice layer
- Image with an electron microscope
- 2D images at unknown orientations -> 3D structure
- Sounds like Structure from Motion (SfM)?

beginframe

- Insert pipeline flowchart

Sounds like SfM?

- Can't detect features from raw images, unlike SfM
- Need new algorithms to handle noise level!

Cryo-EM Pipeline

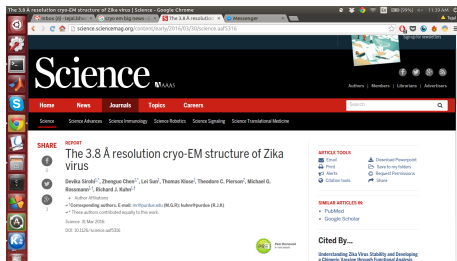

- Can't detect features from raw images, unlike SfM
- Need new algorithms to handle noise level!

Open Source Software

- Insert ASPIRE image
- Open source software toolbox: ASPIRE

Today's talk

- Pipeline figure: highlight denoising, class averaging

Experimental data - 80S ribosome

- FALCON II 4k×4k direct electron detector
- 105247 motion corrected, picked particle images of 360×360 pixels

Experimental data - TRPV1

- K2 direct electron detector
- 35645 motion corrected, picked particle images of 256×256 pixels

Experimental data -IP₃R1

- Gatan 4k×4k CCD
- 37382 picked particle images of 256×256 pixels

Experimental data - 70S ribosome

- TVIPS TEMCAM-F415 (4k x 4k) CCD
- 216517 picked particle images of 250×250 pixels

Cryo-EM Pipeline

- Particle picking from micrographs
- Preprocessing
- 2D classification (Class averaging): inspect underlying particles, estimate viewing angles
- 3D classification
- 3D refinement

- **Outlier detection**

CTF Correction

- CTF suppresses information and inverts contrast
- **Challenge:** CTF cannot be trivially inverted (zero crossings)
- Information lost from one defocus group could be recovered from another group that has different zero crossings.

¹<http://www.bio.brandeis.edu/~shaikh/lab/ctf.htm>

CTF Correction

- CTF suppresses information and inverts contrast
- **Challenge:** CTF cannot be trivially inverted (zero crossings)
- Information lost from one defocus group could be recovered from another group that has different zero crossings.

¹<http://www.bio.brandeis.edu/~shaikh/lab/ctf.htm>

CTF Correction

- CTF suppresses information and inverts contrast
- **Challenge:** CTF cannot be trivially inverted (zero crossings)
- Information lost from one defocus group could be recovered from another group that has different zero crossings.

¹<http://www.bio.brandeis.edu/~shaikh/lab/ctf.htm>

CTF Correction

- Do nothing (Denial)
- Correct Fourier phases but not amplitudes
- Correct both Fourier phases and amplitudes

Current Image Restoration Techniques

- **Phase flipping + steerable PCA (sPCA):**

- Flip sign of the Fourier coefficients at frequencies for which the CTF is negative
- Preserves noise statistics
- Data adaptive basis: eigenvectors of the sample covariance matrix
- Phase flipping corrects only phases

- **Traditional Wiener Filtering (TWF):**

- Corrects both phases and amplitudes
- Requires prior estimation of the spectral signal to noise ratio (SSNR)
- Cannot restore information at zero crossings of the CTF
- Not in a data adaptive basis (restricted to Fourier basis)

Current Image Restoration Techniques

- **Phase flipping + steerable PCA (sPCA):**

- Flip sign of the Fourier coefficients at frequencies for which the CTF is negative
- Preserves noise statistics
- Data adaptive basis: eigenvectors of the sample covariance matrix
- Phase flipping corrects only phases

- **Traditional Wiener Filtering (TWF):**

Covariance Wiener Filtering (CWF)

- Estimate the CTF-corrected covariance matrix of the underlying clean 2D projection images
- Wiener filtering to solve the image restoration deconvolution problem
- No averaging, act on each image separately
- CTF correction and denoising in a single step

Covariance Wiener Filtering (CWF)

- Estimate the CTF-corrected covariance matrix of the underlying clean 2D projection images
- Wiener filtering to solve the image restoration deconvolution problem
- No averaging, act on each image separately

Table : Comparison of CTF Correction/Denoising Methods

| Property | Phaseflip + sPCA | TWF | CWF |
|------------------------------------|------------------|-----|-----|
| Applicable at preliminary stage | ✓ | ✓ | ✓ |
| Data dependent basis | ✓ | ✗ | ✓ |
| Correct both phases and amplitudes | ✗ | ✓ | ✓ |
| CTF corrected covariance estimate | ✗ | ✗ | ✓ |

Fourier-Bessel Steerable Basis

- The population covariance matrix Σ must be invariant under in-plane rotation of the projection images
- Block diagonal in any steerable basis in which the basis elements are outer products of radial functions and angular Fourier modes ²
- CTF and the whitening filter are also block diagonal in the Fourier Bessel basis (radial isotropy)
- Suffices to estimate each diagonal block of Σ , corresponding to the angular frequency k , separately
- Nearly unitary transformation

²Fast Steerable Principal Component Analysis, Z. Zhao and Y. Shkolnisky and A. Singer, IEEE Transactions on Computational Imaging

The Model: Real space

Linear, weak phase approximation

$$y_i = a_i * x_i + \epsilon_i, \quad i = 1, 2, \dots, n \quad (1)$$

n : number of images

$*$: convolution operation

y_i : noisy, CTF filtered i 'th image in real space

x_i : underlying clean projection image in real space

a_i : the point spread function of the microscope

ϵ_i : additive Gaussian noise that corrupts the image

The Model: Fourier space

$$Y_i = A_i X_i + \xi_i, \quad i = 1, 2, \dots, n \quad (2)$$

A_i : diagonal operator, whose diagonal consists of the Fourier transform of the point spread function

X_1, \dots, X_n : vectors in \mathbb{C}^p , where p is the number of pixels
 i.i.d. samples from a distribution with mean $\mathbb{E}[\mathbf{X}] = \mu$ and covariance
 $\mathbb{E}[(\mathbf{X} - \mu)(\mathbf{X} - \mu)^T] = \Sigma$

“All models are wrong but some are useful” - George Box

The Model

$$\mathbb{E}[\mathbf{Y}_i] = A_i \mathbb{E}[\mathbf{X}_i], \quad i = 1, 2, \dots, n. \quad (3)$$

$$\begin{aligned} \mathbb{E}[(\mathbf{Y}_i - \mathbb{E}[\mathbf{Y}_i])(\mathbf{Y}_i - \mathbb{E}[\mathbf{Y}_i])^T] &= \mathbb{E}[A_i(\mathbf{X}_i - \mu)(\mathbf{X}_i - \mu)^T A_i^T] + \sigma^2 I \\ &= A_i \Sigma A_i^T + \sigma^2 I. \end{aligned} \quad (4)$$

Relates the second order statistics of the noisy images with the population covariance Σ of the clean images

Mean Estimation

$$\hat{\mu} = \arg \min_{\mu} \sum_{i=1}^n \|(Y_i - A_i \mu)\|_2^2 + \lambda \|\mu\|_2^2 \quad (5)$$

$$\hat{\mu} = \left(\sum_{i=1}^n A_i^T A_i + \lambda I \right)^{-1} \left(\sum_{i=1}^n A_i^T Y_i \right). \quad (6)$$

Covariance Estimation

$$\begin{aligned}
 \hat{\Sigma} &= \arg \min_{\Sigma} \sum_{i=1}^n \|(Y_i - \mathbb{E}[\mathbf{Y}_i])(Y_i - \mathbb{E}[\mathbf{Y}_i])^T - (A_i \Sigma A_i^T + \sigma^2 I)\|_F^2 \\
 &= \arg \min_{\Sigma} \sum_{i=1}^n \|A_i \Sigma A_i^T + \sigma^2 I - C_i\|_F^2
 \end{aligned} \tag{7}$$

where $C_i = (Y_i - A_i \mu)(Y_i - A_i \mu)^T$ and $\|\cdot\|_F$ is the Frobenius matrix norm.

Solving using Conjugate Gradient

System of linear equations for the elements of the matrix $\hat{\Sigma}$

$$\sum_{i=1}^n A_i^T A_i \hat{\Sigma} A_i^T A_i = \sum_{i=1}^n A_i^T C_i A_i - \sum_{i=1}^n \sigma^2 A_i^T A_i \quad (8)$$

$$L(\hat{\Sigma}) = B \quad (9)$$

where $L : \mathbb{R}^{p \times p} \rightarrow \mathbb{R}^{p \times p}$ is the linear operator acting on $\hat{\Sigma}$ defined by the left hand side of eqn. 8, and B is the right hand side.

- Direct inversion of this linear system is slow for large image sizes
- Applying L only involves matrix multiplications: fast!
- Conjugate gradient

Eigenvalue Thresholding

- $L(\hat{\Sigma})$ is a PSD matrix whenever $\hat{\Sigma}$ is PSD (as a sum of PSD matrices)
- B may not necessarily be PSD due to finite sample fluctuations (n is finite)
- Project B onto the cone of PSD matrices
- Compute the spectral decomposition of B and set all negative eigenvalues to 0 (eigenvalue thresholding)
- $n \gg p$

Eigenvalue Thresholding

- $L(\hat{\Sigma})$ is a PSD matrix whenever $\hat{\Sigma}$ is PSD (as a sum of PSD matrices)
- B may not necessarily be PSD due to finite sample fluctuations (n is finite)
- Project B onto the cone of PSD matrices
- Compute the spectral decomposition of B and set all negative eigenvalues to 0 (eigenvalue thresholding)
- $n \gg p$

Eigenvalue Thresholding

- $L(\hat{\Sigma})$ is a PSD matrix whenever $\hat{\Sigma}$ is PSD (as a sum of PSD matrices)
- B may not necessarily be PSD due to finite sample fluctuations (n is finite)

Eigenvalue Thresholding

- $L(\hat{\Sigma})$ is a PSD matrix whenever $\hat{\Sigma}$ is PSD (as a sum of PSD matrices)
- B may not necessarily be PSD due to finite sample fluctuations (n is finite)
- Project B onto the cone of PSD matrices
- Compute the spectral decomposition of B and set all negative eigenvalues to 0 (eigenvalue thresholding)
- $n \gg p$

Eigenvalue Shrinkage: Spiked Covariance Model

Analyze B when $X_i = 0$ for all i (input images are white noise images)

•

$$M = \sum_{i=1}^n A_i^T C_i A_i = \sum_{i=1}^n A_i^T Y_i Y_i^T A_i. \quad (10)$$

- $\mathbb{E}[M] = \sigma^2 \sum_{i=1}^n A_i^T A_i$ and $B = M - \mathbb{E}[M]$
- $S = (\mathbb{E}[M])^{1/2}$, i.e. S is PSD and $\mathbb{E}[M] = S^2$
-

$$S^{-1} L(\hat{\Sigma}) S^{-1} = S^{-1} (M - \mathbb{E}[M]) S^{-1} = S^{-1} M S^{-1} - I. \quad (11)$$

Eigenvalue Shrinkage: Spiked Covariance Model

- $S^{-1}MS^{-1}$ can be viewed as a sample covariance matrix of n vectors in \mathbb{R}^p whose population covariance is the identity matrix
- Eigenvalues corresponding to the signal can only be detected if they reside outside of the support of the Marčenko Pastur (MP) distribution
- Kritchman Nadler (KN) rank estimation to determine the number of eigenvalues corresponding to the signal ³
- Apply operator norm eigenvalue shrinkage procedure (Donoho et al.) to those eigenvalues, while setting all other eigenvalues to 0 ⁴

³Determining the number of components in a factor model from limited noisy data, Shira Kritchman and Boaz Nadler, Chemometrics and Intelligent Laboratory Systems

⁴Optimal shrinkage of eigenvalues in the spiked covariance model, David Donoho, Matan Gavish and I M Johnstone, arxiv.org/abs/1311.0851

Wiener Filtering

- White noise: estimate X_i as

$$\hat{X}_i = (I - H_i A_i) \hat{\mu} + H_i Y_i \quad (12)$$

where $H_i = \hat{\Sigma} A_i^T (A_i \hat{\Sigma} A_i^T + \sigma^2 I)^{-1}$ is the linear Wiener filter

- Colored noise: estimate X_i as

$$\hat{X}_i = (I - H_i W A_i) \hat{\mu} + H_i Y_i \quad (13)$$

with $H_i = \hat{\Sigma} A_i^T W^T (W A_i \hat{\Sigma} A_i^T W^T + \sigma^2 I)^{-1}$

Computational Complexity

$O(TDL^4 + nL^3)$, where T is the number of conjugate gradient iterations

- D defocus groups with d_i images in group i
- Images of size $L \times L$
- n images

UNIX environment with 60 cores, running at 2.3 GHz, with total RAM of 1.5TB

Relative error of estimated clean images
